

Arduino Smarthome Final

Name - Ryan Heiert

Problem Domain:

The current system for managing google home smarthome systems is a bit limited, and is dependent on google servers.

For example, if the app were to go down, I would lose a bunch of functions. Also, the app is filled with a huge list of devices, when only a couple are relevant to me.

Solution Domain:

An Arduino Nano sending input to a Raspberry Pi with ESPHome, which sends API calls to my personal google home system. This means I have instant fine control over the smart devices in my room without having to pick them out.

Hosting this on my own Pi also means that this solution is more secure and reliable than using the regular app,

Since it would continue working if the app were to go down.

Technologies and Tools:

- ESP32C6 with physical components
- Raspberry Pi 3
- ESPHome (Arduino library for YAML script)
- Google Home devices
